

Abstract

An apparatus and method are directed to managing access to an enterprise resource over a virtual private network by employing a dynamic policy. A client device is configured to log into a network device. The network device receives information about the client device, including information about its configuration and environment. Based, in part, on received information a policy for access is applied to the client device. For example, in one embodiment, the policy may allow only email access from a public kiosk client device, but full intranet access from an enterprise configured client device. The policy may further enable a restriction for the client device that may restrict, for example, what documents may be saved by the client device. In one embodiment, the restriction is enabled using a virtual sandbox.
